

Alexey Navalny Poisoned?

By <u>Stephen Lendman</u> Global Research, August 25, 2020 Region: <u>Russia and FSU</u> Theme: <u>History</u>

Claims by German doctors that Navalny was poisoned appear greatly exaggerated. See below.

Russian political figure with scant public support, sharp Putin critic, Western media darling Navalny supported by the CIA and NED became ill onboard a flight to Moscow.

Rushed to a Omsk, Russia hospital and placed in a medically induced coma, doctors at the facility diagnosed his illness as a metabolic disorder.

US and other Western headlines screamed otherwise, claiming he was poisoned. No traces of poisons were found in his blood or urine.

At the request of family members, he was flown over the weekend to Berlin's Charite Hospital for treatment.

On Monday, a statement by the hospital said the following:

Navalny "is being treated in intensive care and remains in medically induced coma."

"While his condition is serious, it is not currently life-threatening."

"Clinical findings indicate poisoning with a substance from the group of cholinesterase inhibitors."

"The specific substance involved remains unknown, and a further series of comprehensive testing has been initiated."

"The effect of the poison – namely, the inhibition of cholinesterase in the body – was confirmed by multiple tests in independent laboratories."

"As a result of this diagnosis, the patient is now being treated with the antidote atropine."

"Navalny's prognosis remains unclear. The possibility of long-term effects, particularly those affecting the nervous system, cannot be excluded."

"The treating physicians remain in constant contact with Mr. Navalny's wife."

"After close consultation with the patient's wife, Charite is reassured that the decision to make details of the patient's condition public would be in accordance with his wishes."

Cholinesterase inhibitors (ChEIs) "are medications that prevent the breakdown of acetylcholine in the body," Medicinenet explained, adding:

They "block the action of acetylcholinesterase."

"Acetylcholinesterase is an enzyme that breaks down acetylcholine to an inactive form."

"This reduces nerve cell communications in your body that use acetylcholine to help transmit cell to cell messages."

"Doctors prescribe cholinesterase inhibitors to individuals with dementia caused by Alzheimer's disease...Parkinson's disease, glaucoma, myasthenia gravis, and schizophrenia."

The Royal Society of Chemistry said "(n)atural cholinesterase inhibitors (are found in) marine organisms," adding:

They're "common(ly) (used) for the management of several disease states...notably neurological disorders."

They're also found in pesticides and nerve agents.

The Extension Toxicology Network of Cornell, Michigan State, Oregon State, and UC Davis explained the following:

"Cholinesterase (ko-li-nes-ter-ace) is one of many important enzymes needed for the proper functioning of the nervous systems of humans, other vertebrates, and insects."

Unintended "human exposure to cholinesterase inhibiting chemicals can result from inhalation, ingestion, or eye or skin contact."

If "a person receives too great an exposure to cholinesterase inhibiting compounds, the body is unable to break down the acetylcholine."

If Navalny was exposed to cholinesterase inhibitors, it doesn't automatically indicate an attempt to poison him.

He's undergoing further tests to learn more about his condition..

With scant public support in Russia, there's no reason why its authorities would want him poisoned or otherwise harmed.

Establishment media straightaway claimed otherwise.

Like political Russophobes in Washington and London, they invent reasons to bash Russia, providing no evidence backing claims because none exists.

Nothing suggests Kremlin responsibility for Navalny's condition.

Note: Claims by German doctors that Navalny was poisoned were disputed by Russian

doctors.

Russian toxicologists at Omsk "found no toxic chemical substances (in Navalny) that could be called poisons, or their residues."

Navalny tested negative for cholinesterase inhibitors at Omsk, Reuters reported.

RT quoted Omsk region's top toxicologist Alexander Sabayev saying the following:

When Alexey Navalny was admitted to the in-patient clinic, he was examined for a wide range of narcotics, synthetic substances, psychedelic drugs and medical substances, including cholinesterase inhibitors. The result was negative."

German doctors who examined Navalny agreed that their Russian counterparts involved in treating him "saved (his) life."
